Control of acetolactate synthase inhibitor/glyphosate-resistant Palmer amaranth (Amaranthus palmeri) in isoxaflutole/glufosinate/glyphosate-resistant soybean

Jasmine Mausbach1, Suat Irmak2, Debalin Sarangi3, John Lindquist4 and Amit J. Jhala5

Abstract
Palmer amaranth is the most problematic and troublesome weed in agronomic cropping systems in the United States. Acetolactate synthase (ALS) inhibitor and glyphosate-resistant (GR) Palmer amaranth has been confirmed in Nebraska and it is widespread in several counties. Soybean resistant to isoxaflutole/glufosinate/glyphosate has been developed that provides additional herbicide site of action for control of herbicide-resistant weeds. The objectives of this study were to evaluate herbicide programs for control of ALS inhibitor/GR Palmer amaranth and their effect on Palmer amaranth density and biomass, as well as soybean injury and yield in isoxaflutole/glufosinate/glyphosate-resistant soybean. Field experiments were conducted in a grower’s field infested with ALS inhibitor and GR Palmer amaranth near Carleton, Nebraska, in 2018 and 2019. Isoxaflutole applied alone or mixed with sulflentrazone/pyroxasulfone, flumioxazin/pyroxasulfone, or imazethapyr/salufenacil/pyroxasulfone provided similar control (86%–99%) of Palmer amaranth 21 d after PRE (DAPRE). At 14 d after early-POST (DAEPOST), isoxaflutole applied PRE and PRE followed by (fb) POST controlled Palmer amaranth by 10% to 63% compared to 75% to 96% control with glufosinate applied EPOST in both years. A PRE herbicide fb glufosinate controlled Palmer amaranth 80% to 99% 21 d after late-POST (DALPOST) in 2018, and reduced density 89% to 100% in 2018 and 58% to 100% in 2019 at 14 DAEPOST. No soybean injury was observed from any of the herbicide programs tested in this study. Soybean yield in 2019 was relatively higher due to higher precipitation compared with 2018 with generally no differences between herbicide programs. This research indicates that herbicide programs are available for effective control of ALS inhibitor/GR Palmer amaranth in isoxaflutole/glufosinate/glyphosate-resistant soybean.

Introduction
Palmer amaranth is a summer annual broadleaf weed belonging to the Amaranthaceae family and is one of dioecious species among pigweeds (Steckel 2007). Human activities in the 20th century such as agricultural development, within- and between-field operations, and seed and equipment transportation have led Palmer amaranth to spread to the northern United States (Culpepper 2006). Since the first report of Palmer amaranth in Virginia in 1915 beyond its native habitat in the southwest United States, it has become one of the most problematic and troublesome weeds in agronomic cropping systems in the United States (Culpepper et al. 2010). Being dioecious, Palmer amaranth is an obligate outcrossing, wild pollinated species (Sosnoskie et al. 2012), resulting in wide genetic diversity (Jhala et al. 2021; Oliveira et al. 2018). High photosynthetic rate along with diaphlopteric movement (i.e., leaves orienting themselves perpendicularly to incoming sunlight to intercept radiant energy and light) allow Palmer amaranth to fix carbon at higher rate, resulting in rapid growth (Ehleringer and Forsh 1980; Ehleringer 1985). In a 2-yr field study in Kansas, Horak and Loughin (2000) reported that Palmer amaranth had the highest plant dry weight, leaf area, water-use efficiency, and growth rate (0.10 to 0.21 cm per growing degree day) compared to redroot pigweed (Amaranthus retroflexus L.), tumble pigweed (Amaranthus albus L.), and waterhemp [Amaranthus tuberculatus (Moq.) Sauer].

Depending on environmental conditions, Palmer amaranth typically flowers during September and October, although decreasing day length can accelerate the flowering process...
Female Palmer amaranth plants are prolific seed producers, even under competition with agronomic crops (Massinga et al. 2001). Seeds are usually dispersed by gravity forces; however, dispersal via irrigation, plowing, mowing, harvesting, birds, and mammals has been documented (Costea et al. 2004, 2005). Because Palmer amaranth’s prolific seed production and aggressive growth habit make it difficult to control in agronomic cropping systems (Horak and Loughin 2000; Ward et al. 2013), it is vital to control Palmer amaranth early in the growing season by integrating mechanical, cultural, and chemical practices, including PRE herbicides with multiple sites of action (SOAs; de Sanctis et al. 2021; Norsworthy et al. 2012).

Globally, glyphosate is the most widely used agricultural pesticide and is used extensively in glyphosate-resistant (GR) canola (Brassica napus L.), corn (Zea mays L.), cotton (Gossypium hirsutum L.), sugarbeet (Beta vulgaris var. saccharifera), and soybean in the United States (Heap and Duke 2018). Since the commercialization of GR crops, particularly GR corn and soybean in the midwestern United States and GR cotton in the southern United States, continuous use of glyphosate multiple times in a year, along with a decline in the use of residual herbicides (Culpepper 2006; Young 2006), has resulted in the evolution of GR weeds (Beckie 2006).

As of 2020, 50 weeds have been confirmed resistant to glyphosate worldwide (Heap 2021), including six broadleaf weeds such as common ragweed (Ambrosia artemisiifolia L.), giant ragweed (Ambrosia trifida L.), kochia [Bassia scoparia (L.) A. J. Scott], horseweed (Erigeron canadensis L.), water hemp, and Palmer amaranth in Nebraska (Jhala 2017a).

Glyphosate-resistant Palmer amaranth was first confirmed in Georgia in 2004 (Culpepper et al. 2006), and since then has been confirmed in 28 states in the United States (Heap 2021). Palmer amaranth has evolved resistance to herbicides from at least eight SOA groups: microtubule–, acetolactate synthase (ALS)–, 5-enolpyruvyl-shikimate-3-phosphate synthase (EPSPS)–, photosystem II (PS II)–, hydroxyphenylpyruvate dioxygenase (HPPD)–, very long chain fatty acid (VLCFA)–, protoporphyrinogen oxidase (PPO)–, and synthetic auxin inhibitors (Heap 2021). Palmer amaranth resistant to glufosinate was recently confirmed in Arkansas (Barber et al. 2021). Some populations of Palmer amaranth have also been found to have resistance to multiple herbicides in a few states, including ALS inhibitor/glufosinate resistance in Nebraska (Chahal et al. 2017), atrazine/HPPD inhibitor resistance in Nebraska (Jhala et al. 2014), and 2,4-D/ALS inhibitor/atroazine/glufosinate/HPPD inhibitor resistance in Kansas (Kumar et al. 2019).

Palmer amaranth resistance to ALS inhibitors was first confirmed in Kansas in 1994 and since then has been confirmed in 14 states (Heap 2021; Sprague et al. 1997). Isoxaflutole, an HPPD-inhibiting PRE corn herbicide, has been available commercially since 1998 (Spaunhorst and Johnson 2016). The recently available isoxaflutole/glufosinate/glyphosate-resistant soybean (LibertyLink GT27™) provides an opportunity to use isoxaflutole applied PRE alone or in mixture with other residual herbicides for early-season weed control. Glufosinate is a contact, POST herbicide for control of emerged broadleaf and grass weeds (Jhala et al. 2013). It is a nonselective herbicide traditionally used to control weeds in fruit and nut orchards and non-crop areas (Jhala et al. 2013). Norsworthy et al. (2008) reported 99% control of GR Palmer amaranth with glufosinate. Hoffner et al. (2012) found that glufosinate applied early-POST (EPOST) controlled Palmer amaranth by 73% compared to 76% control with glufosinate applied EPOST followed by a late-POST (LPOST). Wiesbrook et al. (2001) found that glufosinate applied sequentially improved control of broadleaf weeds over a single application. Glufosinate applied EPOST resulted in 71% control, and a sequential LPOST application provided 76% control of GR waterhemp in glufosinate-resistant soybean in Nebraska (Jhala et al. 2017). An additional option for POST control of GR Palmer amaranth in glufosinate-resistant soybean is glufosinate mixed with residual herbicides such as acetochlor, pyroxasulfone, or S-metolachlor (Aulakh and Jhala 2015). This mixture provides foliar and residual control of Palmer amaranth through overlapping residual activity.

ALS inhibitor and/or GR Palmer amaranth has been observed in several corn/soybean production fields in south-central and west-central Nebraska, in addition to alfalfa (Medicago sativa L.), corn, and sugarbeet fields in western Nebraska (Vieira et al. 2018). To address the growing need to control GR weeds in cropping systems, multiple herbicide–resistant soybean traits have been developed. For example, isoxaflutole/glufosinate/glyphosate-resistant soybean has been developed to provide an additional herbicide SOA for control of herbicide-resistant weeds, primarily GR weeds; however, herbicide programs need to be developed and tested that provide season-long control of GR Palmer amaranth in this multiple herbicide-resistant soybean. The objectives of this research were to 1) evaluate isoxaflutole- and glufosinate-based herbicide programs for control of ALS inhibitor and GR Palmer amaranth in isoxaflutole/glufosinate/glyphosate-resistant soybean; and 2) evaluate the effect of herbicide programs on Palmer amaranth density and biomass, as well as soybean injury and grain yield.

Materials and Methods

Field Experiments

Field experiments were conducted in 2018 and 2019 in a grower’s field near Carleton, NE (40.30°N, 97.67°W). The field had a GR corn-soybean rotation with reliance on glyphosate for weed control in a no-till production system for the last 10 yr and confirmed to have an ALS inhibitor and GR Palmer amaranth (Chahal et al. 2017). Hereafter, we refer to this as multiple herbicide-resistant (MHR) Palmer amaranth. The soil at the experimental site was silt loam (montmorillonitic, mesic, Pachic Argiustolls), pH 6.0; and 19% sand, 63% silt, 18% clay, and 2.6% organic matter content. Winter annual weeds were controlled with glyphosate at 900 g ae ha−1 + 2.4-D ester at 560 g ae ha−1 + liquid ammonium sulfate 3% vol/vol 2 wk prior to establishing an experiment. A soybean cultivar resistant to isoxaflutole/glufosinate glyphosate was planted in a no-till seedbed at 345,800 seeds ha−1 in rows spaced 76 cm apart. Soybean was planted on May 10, 2018, and May 6, 2019. Individual experimental plot dimensions were 3 m wide by 9 m long. The experimental site was in a rainfed environment with no supplemental irrigation. The precipitation received during both years during crop growing season are listed (Table 1).

Treatments were arranged in a randomized complete block design with four replications. Herbicide programs evaluated to control MHR Palmer amaranth consisted of PRE, EPOST, LPOST, and/or PRE fb POST herbicide programs (Table 2). A nontreated control was included for comparison. Herbicides were applied with a hand-held CO2–pressurized backpack sprayer equipped with AIXR 110015 flat-fan nozzles (TeeJet Technologies, Wheaton, IL) calibrated to deliver a 140 L ha−1 flow rate at 276 kPa at a constant speed of 4.8 km h−1. Glufosinate was mixed with liquid ammonium sulfate at 3% vol/vol (Anonymous 2017) and was applied with XR 11005
flat-fan nozzles (TeeJet® Technologies). The PRE herbicides were applied after soybean planting on the same day (i.e., May 10) in 2018, and 4 d after soybean planting (i.e., May 10) in 2019. The EPOST herbicides were applied 31 d after PRE (DAPRE) herbicides were applied. Palmer amaranth was 1 to 8 cm tall depending on herbicide program. Soybean was at the first to second trifoliate (V1 to V2 growth stage). The LPOST herbicides were applied 20 to 22 DAEPOST herbicide application. Palmer amaranth was 8 to 25 cm tall depending on the herbicide program. Palmer amaranth plant height was variable because new plants had emerged and some plants had been partially controlled by the EPOST herbicide.

aData were obtained from National Oceanic and Atmospheric Administration (NOAA 2019).

### Results and Discussion

Year-by-treatment interaction for MHR Palmer amaranth control 21 DAPRE was not significant (P > 0.05); therefore, data were combined for both years, while Palmer amaranth control estimates 14 DAEP0ST and 28 DALPOST, Palmer amaranth density, and soybean yield were significant (P < 0.05); therefore, data were presented separately for both years. No soybean injury was observed from any herbicide program (data not shown), indicating that the herbicides evaluated in this study are safe to use in isoxaflutole/glu- fosinate/glyphosate-resistant soybean when applied according to label instructions. Schultz et al. (2015) also reported that isoxaflutole is safe to use in isoxaflutole-resistant soybean.

### Temperature and Precipitation

The 2018 growing season started off warmer than average, with temperatures of 20.6 and 25.0 °C for May and June, respectively, compared with 14.8 °C and 21.8 °C in 2019 (Table 1). Monthly precipitation varied from the 30-yr average in both years. Below-average precipitation occurred in 2018, with 78 and 96 mm in May and June, respectively, compared with the 30-yr average of 135 and 115 mm, whereas above-average precipitation was observed throughout the 2019 growing season (Table 1).

### Palmer Amaranth Control

The PRE herbicides evaluated in this study controlled MHR Palmer amaranth by 86% to 99% 21 DAPRE (Table 3). Although statistically similar with other PRE herbicides, pyroxasulfone/sulfentrazone, flumioxazin/pyroxasulfone, and imazethapyr/pyroxasulfone/saflufenacil controlled Palmer amaranth by 97% to 99%. The contribution of the ALS-inhibiting herbicide (i.e., imazethapyr) was minimal; rather, the VLCFA inhibitor (i.e., pyroxasulfone) and PPO-inhibitor (i.e., saflufenacil) primarily contributed to the control. Shyam et al. (2021) reported similar findings 14 DAPRE with imazethapyr/pyroxasulfone/saflufenacil, when Palmer amaranth control ranged from 87% to 97% in a 2-yr study in 2,4-D choline/glufosinate/glyphosate-resistant soybean. Sarangi and Jhala (2019) reported at least 98% Palmer amaranth control 14 and 28 DAPRE with imazethapyr/dimethenamid-P/saflugenacil and flumioxazin/pyroxasulfone. Isoxafluotole applied PRE controlled Palmer amaranth by 86% to 89% 21 DAPRE (Table 3); however, variable control of Palmer amaranth has been reported with isoxafluotole in the literature. Meyer et al. (2016) and Johnson et al. (2012) reported at least 87% Palmer amaranth control 14 and 28 DAPRE with imazethapyr/dimethenamid-P/saflugenacil and flumioxazin/pyroxasulfone. Isoxafluotole requires 12.7 to
25.4 mm of irrigation or rain to activate, although too much water can cause the herbicide to become diluted and leach, thus reducing its efficacy (Jhala 2017b). If moisture is adequate, isoxaflutole can provide 14 to 21 d of residual activity for Palmer amaranth control (Chahal et al. 2015).

Palmer amaranth control varied between years with a PRE fb EPOST herbicide programs (Table 3). Glufosinate applied alone controlled MHR Palmer amaranth 95% to 96% in 2018 and 75% in 2019. Glufosinate mixed with isoxaflutole controlled Palmer amaranth 92% to 95% in 2018 and 85% to 94% in 2019 (Table 3). Shyam et al. (2021) reported 88% Palmer amaranth density reduction with flumioxazin/pyroxasulfone in soybean in a multiyear, multistate study, while Sarangi (2012) reported greater than 80% late-season control of GR Palmer amaranth with flumioxazin/S-metolachlor applied PRE fb fomesafen, although less than 30% late-season control was achieved with flumioxazin/S-metolachlor without fomesafen applied POST. A single herbicide application is less likely to provide a season-long control of Palmer amaranth and a PRE followed by a POST herbicide program is required for effective control and reducing Palmer amaranth seedbank (Norsworthy et al. 2012).

At 28 DALPOST, isoxaflutole applied PRE or in sequential applications (PRE fb EPOST) controlled MHR Palmer amaranth by 10% and 53% in 2018, respectively, while providing no control in 2019 (Table 3). This indicates that isoxaflutole applied alone or in mixture with other herbicide(s) is needed to achieve economically acceptable control. In this study isoxaflutole applied at 105 g ai ha⁻¹ will not provide effective control later in the growing season and that mixture with other herbicide(s) is needed to achieve economically acceptable control. In this study isoxaflutole was applied at 105 g ai ha⁻¹; however, it can be applied in a range of 140 to 210 g ai ha⁻¹ in a single application with a season maximum of 210 g ai ha⁻¹ (Anonymous 2020). Relatively lower use rate in this study is because the study was conducted before isoxaflutole label approved in 2020. In addition, isoxaflutole is primarily a residual herbicide with limited foliar activity; therefore, effective control of emerged Palmer amaranth at the time of application should not be expected. Janak and Grichar (2016) reported similar findings of 51% Palmer amaranth control with a single application of isoxaflutole 101 DAPRE. When mixed with metribuzin, isoxaflutole has been shown to provide 97% to 98% control of redroot pigweed and Powell amaranth (Amaranthus powellii S. Watson; Smith et al. 2019). With the exception of isoxaflutole, PRE fb POST herbicide programs provided 80% to 99% MHR Palmer amaranth control in 2018 and 78% to 99% control in 2019 at 28 DALPOST (Table 3). Whitaker et al. (2010) reported greater than 80% late-season control of GR Palmer amaranth with flumioxazin/S-metolachlor applied PRE fb fomesafen, although less than 30% late-season control was achieved with flumioxazin/S-metolachlor without fomesafen applied POST. A single herbicide application is less likely to provide a season-long control of Palmer amaranth and a PRE followed by a POST herbicide program is required for effective control and reducing Palmer amaranth seedbank (Norsworthy et al. 2012).

### Table 2. Herbicides, application timings, and rates used for control of acetolactate synthase inhibitor and glyphosate-resistant Palmer amaranth in isoxaflutole/glufosinate/glyphosate–resistant soybean in field experiments conducted in 2018 and 2019.

*aGlufosinate was mixed with ammonium sulfate (DSM Chemicals North America Inc., Augusta, GA) at 4.2 kg ha⁻¹.
Herbicides applied PRE fb glufosinate reduced MHR Palmer amaranth density by at least 87% in 2018 and 2019. Similar findings were reported by Shyam et al. (2021) and Norsworthy et al. (2016). Glufosinate alone reduced MHR Palmer amaranth density 89% and 58% in 2018 and 2019, respectively, whereas glufosinate mixed with isoxaflutole reduced density by 63% to 100% in 2018, and 85% to 94% in 2019 (Table 4). Chahal and Jhala (2015) reported 50% waterhemp density reduction with glufosinate applied EPOST; and 83% density reduction with glufosinate applied EPOST fb LPOST 45 DALPOST in glufosinate-resistant soybean in Nebraska.

At 14 DALPOST in 2019, PRE herbicide fb glufosinate applied EPOST reduced MHR Palmer amaranth biomass by 49% to 97% compared to 95% biomass reduction with glufosinate applied LPOST (Table 4). Aulakh and Jhala (2015) reported 79% to 88% weed biomass reduction with dimethenamid-P/saflufenacil, or imazethapyr/sulfentrazone fb glufosinate. Shyam et al. (2021) reported 100% Palmer amaranth biomass reduction with imazethapyr/pyroxasulfone/saflufenacil fb glufosinate and 99% biomass with glufosinate applied EPOST followed by LPOST in 2,4-D choline/glufosinate/glyphosate–resistant soybean. Single or sequential applications of isoxaflutole resulted in no biomass reduction due to poor Palmer amaranth control (Table 4). Chahal and Jhala (2015) reported 80% to 91% and 92% to 95% biomass reduction with glufosinate applied in single and sequential applications, respectively, in glufosinate-resistant soybean. Thus, a PRE herbicide with multiple SOAs fb glufosinate has consistently provided >90% control of Palmer amaranth and >90% density and biomass reduction in most studies.

### Soybean Yield

Year-by-treatment interaction was significant (P < 0.05); therefore, yield data are presented separately for both years (Table 4). Soybean yield in 2019 was higher compared to 2018 due to higher precipitation in 2019 that provided sufficient moisture for soybean growth and development (Table 1). Isoxaflutole mixed with pyroxasulfone/sulfentrazone applied PRE fb glufosinate had soybean grain yield of 2,290 kg ha\(^{-1}\) in 2018, and it was comparable with several herbicide programs (Table 4). In 2019, several herbicide programs resulted in similar soybean yield in the range of 3,140 to 4,282 kg ha\(^{-1}\) (Table 4). Shyam et al. (2021) reported soybean yields with similar PRE herbicides used in combination with glufosinate.

### Practical Implications

A new soybean trait resistant to isoxaflutole/glufosinate/glyphosate has been available commercially since the 2019 growing season in the United States. Results of this study suggest that herbicide programs are available for effective control of MHR Palmer amaranth in isoxaflutole/glufosinate/glyphosate–resistant soybean. No soybean injury was observed with any of the herbicide programs evaluated in this study, including isoxaflutole applied in sequential applications. Isoxaflutole (Alite™ 27) was registered in 2020 for application in isoxaflutole-resistant soybean; however, use of this herbicide is limited to certain counties in a few states. For example, isoxaflutole (Alite™ 27) is labeled for application in only four southwest counties (Chase, Dundy, Hitchcock, and Red Willow) in Nebraska (Anonymous 2020). In addition, isoxaflutole cannot be applied on coarse-textured soils (e.g., sandy, sandy loam, loamy sand) with less than 1.5% organic matter content, limiting the use of this herbicide. The majority of soybean in Nebraska is grown in eastern Nebraska, so although growers can plant isoxaflutole/glufosinate/glyphosate–resistant soybean in this region, they cannot use isoxaflutole (Alite™ 27) due to label restriction (Anonymous 2020). Therefore, adoption of soybean resistant to isoxaflutole/glufosinate/glyphosate in Nebraska will likely be very limited.
### Table 4. Effect of herbicide programs on glyphosate-resistant Palmer amaranth density reduction and biomass reduction and isoxaflutole/glufosinate/glyphosate-resistant soybean yield in field experiments conducted in 2018 and 2019.

</tbody>
</table>

<sup>a</sup>Abbreviations: DAEPOST, days after early-POST herbicide application; DALPOST, days after late-POST herbicide application; fb, followed by.
<sup>b</sup>Year-by-treatment interaction for glyphosate-resistant Palmer amaranth density and soybean yield were significant; therefore, data were not combined across the two years.
<sup>c</sup>Biomass reduction data is only available for 2019.
<sup>d</sup>Hens presented within each column with no common letter(s) are significantly different according to Fisher’s protected least significant difference test at P ≤ 0.05.

### Acknowledgments
We thank Irvin Schleuffer, Will Need, Jose H. Sanits, and Adam Leise for their assistance with the project and Jan Rogers for editing the manuscript. This project was partially supported by the Nebraska Agricultural Experiment Station with funding from the Hatch Act through the U.S. Department of Agriculture–National Institute of Food and Agriculture Project # NEB-22-396. This project was also supported by the Nebraska Soybean Board. No conflicts of interest have been declared.
